** Add 10" to depth of CLD, CLDO, and CLDW and 15" to depth of CLDX for control box overhang.

H – Height excludes expansion tank.

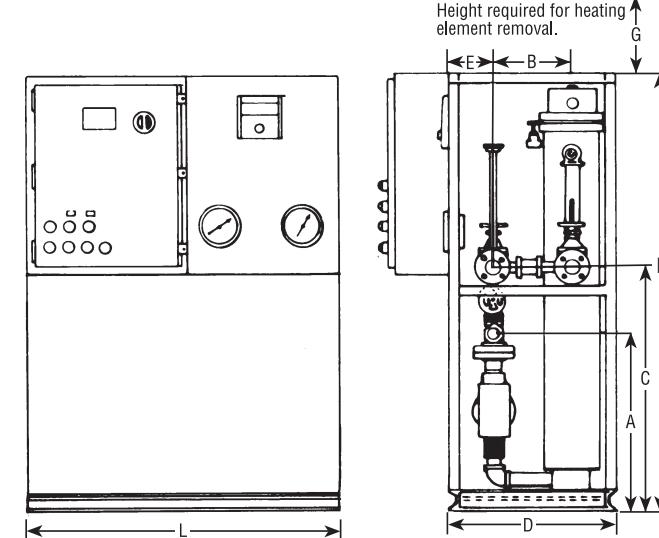

Expansion tank specifications and dimensions

The expansion tanks used with the CLD line of hot oil heat transfer systems are ASME Rated for 150 psi at 650°F. They are made of carbon steel and come complete with 3/4" – 300 lb. flanged inlet connections, ASME relief valve and a sight glass assembly.

Size Gal.	Dimensions				E	F	Empty Wt. (Lbs.)

Optional Liquid Level Control for Expansion Tank

This optional liquid level control or float switch is mounted on the expansion tank and is used for automatic shutdown of the heat transfer system in case of low liquid level. It can be used with most of the heat transfer fluids having a minimum specific gravity of 0.85.

GENERAL

The Chromalox Heat Transfer Unit is a thoroughly engineered, pretested package, designed to give years of service, virtually maintenance free if properly installed. The CLD series can operate at 750°F at 150 psi. (depending upon heat transfer fluid properties) and is available in four models, each with basic features that comply with the National Electrical Code. Model CLD has general-purpose NEMA I construction and can be used where no hazards exist. Model CLD W can be used where weather-resistant construction is required and is constructed according to NEMA IV specifications.

Model CLDO is oil and dust tight as specified by NEMA XII standards. Model CLDX, Class I, Group D, Division I is explosion resistant and is constructed to operate in hazardous or explosive areas. (**Warning:** Pipe surfaces could achieve temperatures higher than allowed for Class I, Group D, Division 1 hazardous areas). Common to all four models: steel heater sheath, maximum density 22 watts per square inch; cast steel centrifugal pump; power requirements 208, 240, 480 and 550 volts, 3 phase, 60 cycles, 9 thru 400kW.

INSTALLATION

CAUTION: This system is not for use with water, ethylene glycol and water mixture or some of the synthetic heat transfer fluids. Check with your local Chromalox Sales and Application Engineer to be sure you are using an accepted heat transfer medium in this system and request PQ301.

Note: When installing system allow sufficient room to remove element if and when necessary. (See dimensional table column G Page 2)

HYDRAULIC:

Note: The CLDW systems should be mounted so the control box does not fall in direct sunlight.

The bed plate should be mounted on a solid foundation, preferably level.

The pipe size should be the same as the system piping connections. All piping must be supported so the pump is not carrying any of the pipe weight. If these instructions are **not** followed, distortion in the pump may cause unnecessary wear and faulty operation.

1. The piping of the entire system should be arranged to minimize pockets where air may be trapped. Manual air vents or bleeder valves should be provided in the system where air pockets may occur and every time the flow of fluid drops.
2. Mount the expansion tank so it is the highest point in the system and if possible at least 15 feet above the height of the pump. Connect the fluid level sight glass to the expansion tank. To safeguard employees and equipment, run the relief line out of the building. This relief line should be the same size as the relief valve discharge.

When the system is going to operate above THE boiling temperature of the heat transfer fluid, the expansion tank will have to be pressurized with air or nitrogen. This eliminates the possibility of heat transfer fluid flashing into vapor in the heater, at the point of high velocity in the system, at the suction of the pump or causing the pump to vapor lock due to insufficient NPSH (net positive suction head). On hot oil heat transfer system, this pressurizing is usually done with nitrogen as this eliminates the possibility of the hot fluid coming in contact with oxygen thus reducing the possibility of oxidation, extending the life of the heat transfer fluid. This pressure should be 5-10 PSI above the vapor pressure of the heat transfer fluid at its operating temperature. The expansion tank is to be pressurized, and must be equipped with safety relief valve(s). The heat transfer system and expansion tank should be ASME coded.

3. **Pump Alignment** – The pump and motor have been carefully aligned and tested at the factory. However, they should be checked for alignment after the unit is permanently mounted since movement and vibration in transit can throw them out of alignment. Alignment should be made when unit is cold but alignment should be rechecked after system is operating. If out of alignment again final alignment should be made when system is at normal operating temperature. Follow the alignment procedures recommended by the pump manufacturer.

4. **Pump Cooling** – This system is furnished with a high-temperature centrifugal pump that requires water cooling of the bearing journal and mechanical seal. To provide this water cooling, connect water supply and drain lines to the unions provided on the system.
 - a. **BEARING JOURNALS** – The flow should be adjusted by using the valve supplied on the system to maintain a temperature range of 120°F to 200°F in the bearing housing. Approximate flow should be 2 GPM.

- b. **MECHANICAL SEAL** – the seal requires a water flow rate of approximately 1/2 GPM. **Note:** There should be no leakage of the heat transfer fluid at the seal. **CAUTION:** Do not rotate pump when the seal is dry as seal could be damaged.

5. **Pump Lubrication** – **CAUTION:** Pumps are shipped from the factory without oil in the bearing housing.

- a. Lubrication of ball type radial and thrust bearings in the pump is by oil contained in the sump of the bearing housing. The oil level is controlled by a constant level oiler of a fixed height setting. Failure to level the assembly when the unit is installed may adversely affect this level and cause damage to pump bearings. Use a good grade SAE-20 oil to fill the oil reservoir. Remove the oil reservoir cup of the constant level oiler and pour oil through the oil reservoir cup until the oil can be seen at the bottom. Fill the oil reservoir cup and put it back into place. The oil will bubble into the bearing housing until the proper level has been reached. Remove the oil reservoir and after refilling it, put it back into place. Thereafter the oil level remains constant as long as some oil remains in reservoir cup.
- b. The top of the bearing housing is fitted with a screened vent plug to provide the necessary ventilation. It is not an oil fill plug and the bearing housing should never be filled through this opening.
- c. The oil should be drained and relaced at regular intervals, the intervals depend on the atmospheric conditions (dust, soot, corrosive vapors, humidity, temperature variations, etc.) prevailing at the pump installation site. The bearing housing should be flushed with a good solvent before the oil is replaced.

6. Flanged connections and motor mounts sometimes loosen during transit. Check and tighten if necessary.

ELECTRIC:

CAUTION: Hazard of Electric Shock. The heat transfer system must be grounded using grounding means provided in control box and employing wiring in accordance with National Electrical Code.

1. The unit is completely wired. The only wiring necessary is to terminals L1, L2, and L3 on the main circuit breaker and the ground lug in the control panel.

CAUTION: Hazard of Electric Shock. Disconnect all power before servicing the heat transfer system.

2. Turn the thermostat(s) to the lowest temperature possible and the ON-OFF Selector Switch(es) to the OFF position. Start the unit by pushing the push button marked START, located on the front of the panel. This test is to check pump rotation and the unit should be turned off immediately upon learning the direction of rotation.
3. The pump rotation should be as indicated by arrows on motor. If direction of rotation is wrong, reverse the input leads (L1 and L3) at the master circuit breaker. Momentarily start the pump to check rotation.
4. All electrical connections should be checked and tightened if necessary. These sometimes loosen during transit.

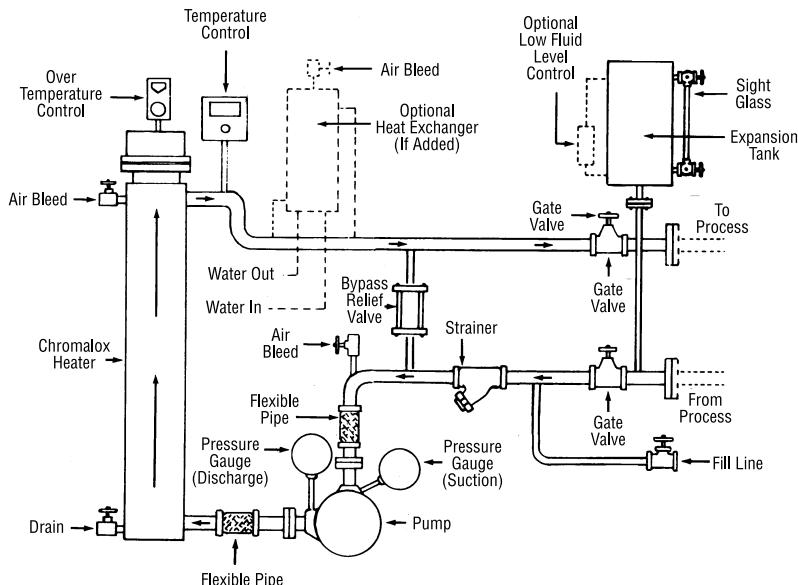

OPERATION

CAUTION: To avoid possible damage to the heaters, DO NOT energize the heater until the system is filled with fluid.

1. All systems are pretested using Mobiltherm®. (System can be pretested with other fluids. Check with your local Chromalox Sales & Application Engineer). Check to insure your fluid is compatible with fluid used in pretest.
2. On systems equipped with a float switch on the expansion tank it will be necessary to bypass this switch until the system is filled in order to operate the pump. After system is filled remove bypass jumper to obtain protection of float switch. This switch will shut the system down in the event of a low liquid level or loss of heat transfer liquid thus preventing damage to system.

3. You are now ready to start filling the system with heat transfer fluid. Close the system inlet gate valve and open the outlet and fill line gate valves and heater bleed valve on all heaters. Prime the pump by pouring approximately 1 pint to 1 quart of fluid through the 1/4" air bleed valve located above pump. (Close this 1/4" air bleed valve and leave closed while pump is in operation.)
4. The system is then filled directly from the 55 gallon drum(s) by connecting a hose to fill line and inserting it into the drum.
5. Next, energize the pump to pull the fluid into the complete system and up into the expansion tank. When the fluid reaches the heater bleed valve, it should then be closed, and accordingly the bleeds on the customer's process closed when the fluid reaches them.

Typical piping schematic of a Chromalox heat transfer system

The fill line remains open until the expansion tank sight glass indicates being 1/3 full. After the system is filled, shut down the pump and close the fill valve. Open system inlet valve.

WARNING: Avoid having the heat-transfer fluid spilled or leaked into the pipeline insulation as it has been found that spontaneous ignition of this fluid may result at elevated temperatures.

6. Turn master circuit breaker off. Bleed air from all lines (including one located above pump) and reclose all bleed valves.
7. If included in your system, locate the optional pressure switch inside the control panel. It should be set approximately three pounds higher than that indicated by the suction gauge. The pressure switch is a safety control which will automatically de-energize the heaters if the pump belt should break and stop the flow of fluid.
8. The overheat thermostats, also located inside the control panel should be checked to insure manual reset buttons are in the closed position. They should be set approximately 50°F higher than the control thermostat during normal operation.
9. Close control box door and turn circuit breaker on. Start pump – do not be alarmed if the pump is noisy during the initial start-up operation since it is due to air in the system.
10. Bleed out all air by opening bleeder valves. The pump should become quiet.

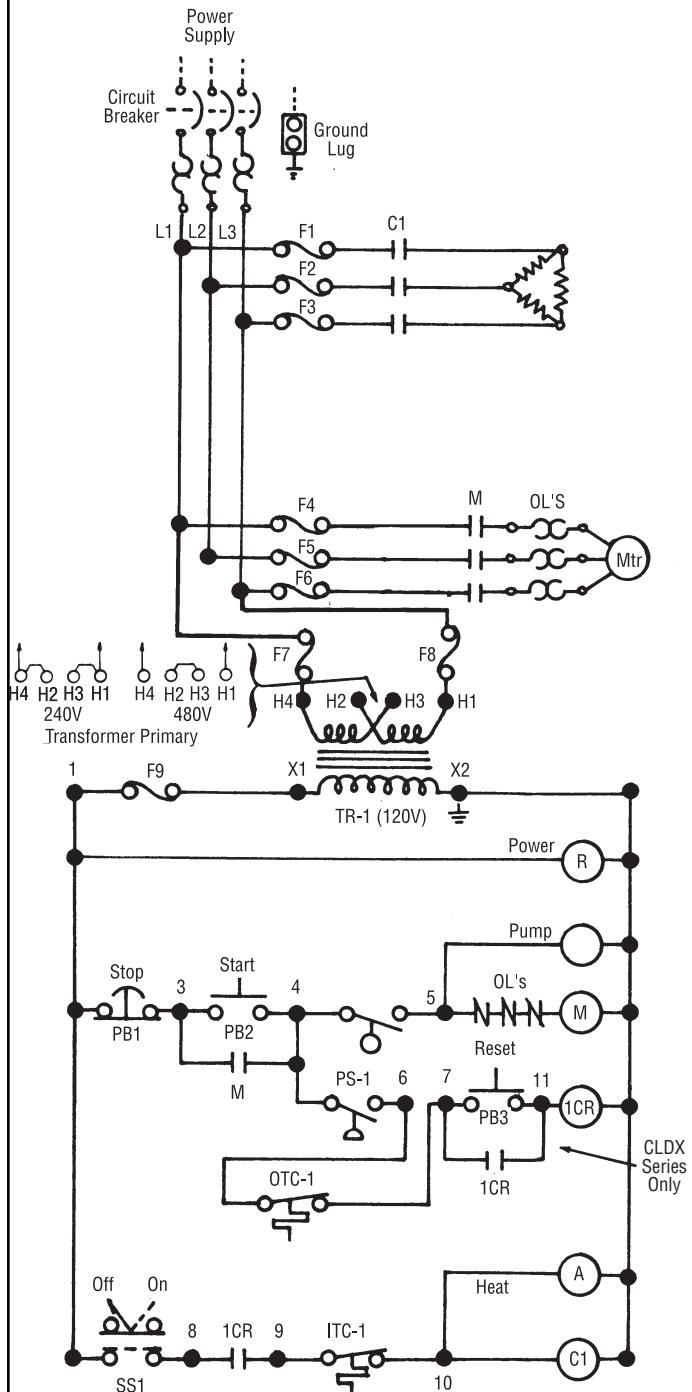

CAUTION: During the initial start-up operation, the liquid level in the expansion tank must be checked continually. This level should not exceed the three-quarter mark on the glass nor drop below the one-quarter mark. **Note:** If abnormal expansion of fluid is detected, this is probably due to a pocket of air or steam still present in the system. Check all bleed valves for air or steam and bleed if necessary. If problem continues, de-energize pump and bleed again.

11. On systems equipped with a flow switch, the liquid must be flowing at a minimum of 75% of rated pump capacity in order to close the flow switch and energize the heater.
12. Set indicating or controlling thermostat at 220°F.
13. To energize the heater, turn the ON-OFF selector switch to the ON position after starting the pump. The heater is interlocked with the pump motor starter so that, in the event of motor failure, the heating elements will shut off automatically.
14. Run the system until 220°F is reached. Periodically open the bleeder valves to remove air from the system. At 220°F, any moisture trapped in the system will flash into steam as it goes through the heater and can be bled out through the bleeder valves.
15. Excessive moisture and air in the system will cause the heat transfer liquid to back up into the expansion tank, thus evacuating the heating chamber or chambers. If this happens, shut the system down, bleed off the steam and air and allow liquid to return to the heating chamber(s). Drain the system and recharge with new moisture-free heat transfer liquid. If pump continues to be noisy and cavitates or if abnormal expansion persists there is excessive moisture in the fluid.
16. After the system has been completely charged and free of air pockets, set controlling thermostat at the desired temperature.
17. If there is an abnormally low reading (less than zero) on the suction gauge, the strainer should be cleaned to remove all foreign material which may have accumulated during assembly. After the system is in operation, the strainer should be checked and cleaned (if necessary) once a year or more frequently if system operating conditions dictate.

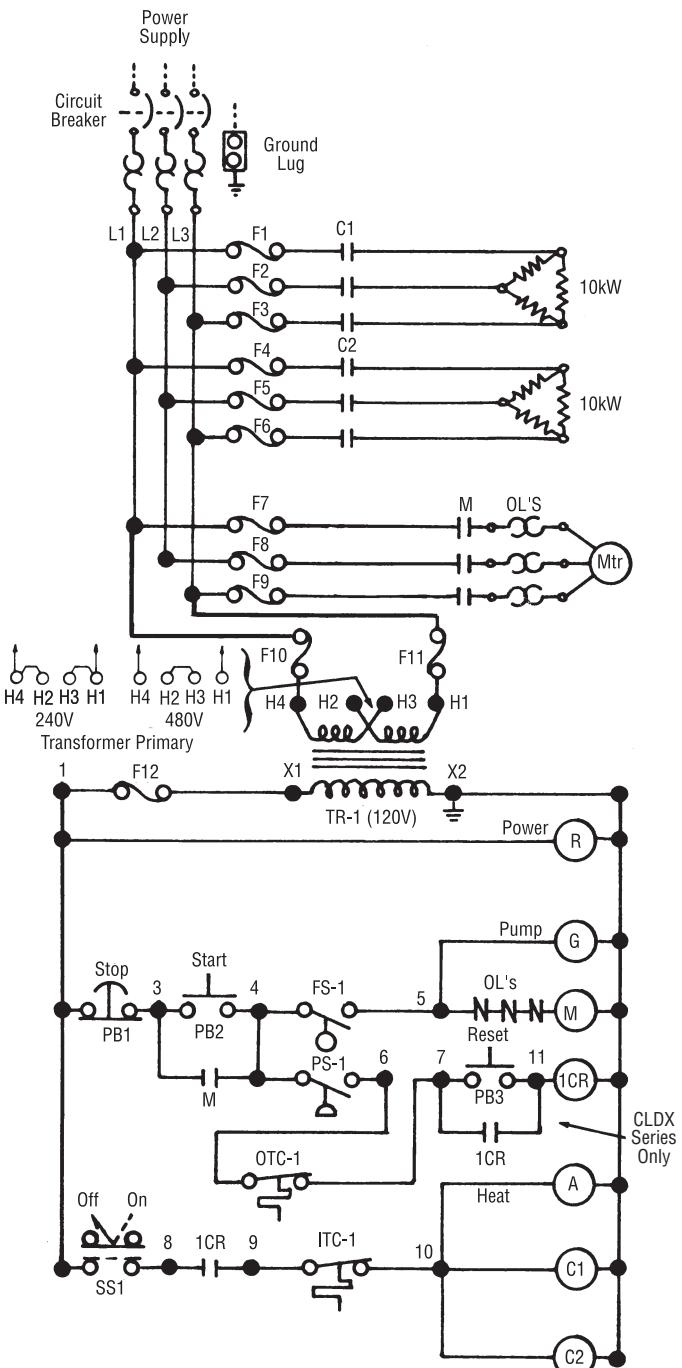

Note: Consult Service Manual PQ410 for additional aid to help start-up and to service Chromalox Heat Transfer Systems.
